Infants at elevated likelihood of autism spectrum disorder: Language development patterns and caregiver coaching strategies

This presentation will include two studies focused on the early development of infants at an elevated likelihood of an autism spectrum disorder diagnosis. In the first study, the language profiles (i.e., receptive dominant, expressive dominant, balanced) and the predictors of the language profiles are examined in infants at EL-ASD. The second study explores the coaching behaviors demonstrated by interventionists in a parent-mediated intervention for infants at EL-ASD. Together, these studies aim to add to the research focused on early interventions for children at an elevated likelihood of an autism spectrum disorder diagnosis.
